ABSTRACT

The main purpose of this paper is to present some researches regarding the composite micropowders with wolfram matrix in mixture with copper used in production of the electrical contacts. In order to alloy the two powders, the mechanical alloying is used. The SEM micrograph of the tungsten micropowder and copper and then the SEM micrograph of the mixture WC-Cu for the different mechanical alloying time are presented.

Keywords: Micropowders, copper, mechanical alloyed, SEM micrograph

1. INTRODUCTION

Copper alloys are one of the most commonly used materials for various engineering applications, although one of the factors limiting the wider application of copper and copper alloys is from the one hand relatively low mechanical strength and on the other hand the large density. Silicon carbide (SiC) is recognized as one of the potential candidates for electronic packaging and thermal management applications. Metal matrix composite materials reinforcement by Al₂O₃ were developed by various methods and also found wide application where the high electrical conductivity, high thermal conductivity and high strength and low wear resistance are required.

Composite material WC/Cu is applied as the electrical contacts, resistance welding electrodes and electrodes for automatic welding.

One of the most technique to alloy the WC powder an Cu powder is mechanical alloying, a recent technique used for this materials, [1], [5].

Copper tungsten sintered materials are manufactured with different copper contents, from 20% up to 70%, depending on the use to which they are put, [3]. The method of manufacture depends on the percentage of tungsten present. Materials with large percentages of tungsten (around 80%) are generally made by the impregnation process, where it is advantageous to use a coarse grain tungsten powder to decrease arc erosion. For percentages of the order of 60%, liquid phase sintering is more appropriate, and for materials with less tungsten, powder mixtures without a liquid phase are sintered together.

Materials with a low copper content are used for high currents to improve contact life and breaking capacity. With a higher copper content, about 67%, the material erodes slightly less than pure copper, at low currents (around 20 amp), and the improvement in erosion resistance is enhanced at higher currents, but this is accompanied by considerable deformation of the contact surface. The contact resistance increases considerably on arcing, due to oxidation and depletion of copper in the interface.

The lack of solubility of W in Cu makes W-Cu a model system for liquid phase sintering because densification can be attribute to either particle rearrangement or solid-state sintering of the skeletal structure, [7].

The final shape and, also, the physical and mechanical characteristics of the micropowders are obtained through the microwave technique, the known as a very useful technique for this type of refractory materials, [2], [6].
2.2. POWDER CHARACTERISTICS

2.1. Copper powder

In order to elaborate the composites materials with tungsten micropowder matrix and copper for electrical contacts the next powder type was used (tables 1 and 2 for copper powder and tables 3 and 4 for tungsten powder). The copper powder was SEM characterization using an electronic microscope, FEI – INSPECT from INFLPR Bucharest, and are presented in figs. 1, 2, 3 and 4.

![Fig. 1. SEM micrograph for 1000x](image1)

![Fig. 2. SEM micrograph for 2500x](image2)

![Fig. 3. SEM micrograph for 5000x](image3)

![Fig. 4. SEM micrograph for 10000x](image4)

Due to the electrolytic process, the shape of copper powder can be characterized as dendrite.

2.2. Tungsten powder

In this paper K30 powder type was used with the chemical composition presented in table 3, and SEM micrograph for different magnification in figs. 5 to 8.

3. MECHANICAL ALLOYING

In order to elaborate the tungsten nanopowders a mechanical alloying technique and Pulverisette 6 vario-planetary ball mill were used.

The working process parameter was:
- bowl volume: 250 ml;
- bowl material: stainless steel;
- ball diameter: Φ=10 mm;
- balls number: 50 pieces;
- balls material: stainless steel;
- material/ball ratio: ½ (100gs powder K30+Cu and 200 gs, balls);
- alloying environment: air
- alloying times: 5, 10, 15 hours

Table 4 shows the concentration of copper and tungsten powders for mechanical alloying.

In order to mechanical alloying nine samples was prepared: 3 samples K30 (65%)-Cu(35%), using three time for mechanical alloying: 5,10 and 15 hours; 3 samples K30 (70%)-Cu(30%), using three time for mechanical alloying: 5,10 and 15 hours; 3 samples K30 (75%)-Cu (25%), using three times for mechanical alloying: 5, 10 and 15 hours.

The ration of mixture was done using a precision analytical balance WPS 510. The weigh of each sample is 100 gs.

5. CONCLUSIONS

In order to elaborate the W - Cu nanostructured powders the mechanical alloying technique was used;

From SEM analysis it is observed that the particles are agglomerated specially at higher times of mechanical alloying. There are the difference between copper particles and tungsten particles;

The shape for all the three samples obtained after 8 hours of mechanical alloying by friction mode respectively shock mode is irregular.
